PhenoCam Dataset v2.0: Vegetation Phenology from Digital Camera Imagery, 2000-2018

Get Data

Documentation Revision Date: 2019-04-16

Dataset Version: 2

Summary

This data set provides a time series of vegetation phenological observations for 393 sites across diverse ecosystems of the world (mostly North America) from 2000-2018. The phenology data were derived from conventional visible-wavelength automated digital camera imagery collected through the PhenoCam Network at each site. From each acquired image, RGB (red, green, blue) color channel information was extracted and means and other statistics calculated for a region-of-interest (ROI) that delineates an area of specific vegetation type. From the high-frequency (typically, 30 minute) imagery collected over several years, time series characterizing vegetation color, including canopy greenness, plus greenness rising and greenness falling transition dates, were summarized over 1- and 3-day intervals.The PhenoCam data are released under a CC-BY license.

The data products, consisting of almost 1783 site-years of observations, can be used for phenological model validation and development, evaluation of satellite remote sensing data products, to understand relationships between canopy phenology and ecosystem processes, to study the seasonal changes in leaf-level physiology that are associated with changes in leaf color, for benchmarking earth system models, and for studies of climate change impacts on terrestrial ecosystems.

This data set contains 393 network site descriptions files (in both *.txt format and *.JSON format), 1500 region-of-interest definition (ROI) files in TIFF format, 3168 *.csv files, including ROI index files, and time series of extracted image color and greenness transitions processed to 1- and 3-day intervals.

Figure 1. PhenoCam Network image from the Coweeta, North Carolina site. The region of interest (ROI) at the time this image was acquired was the transparent area with deciduous vegetation in the foreground.

1. Dataset Overview

This data set provides time series of vegetation phenological observations for 393 sites across diverse ecosystems of North America and Europe from 2000-2018. The phenology data were derived from conventional visible-wavelength automated digital camera imagery collected through the PhenoCam Network at each site. From each acquired image, RGB (red, green, blue) color channel information was extracted and means and other statistics calculated for a region-of-interest (ROI) that delineates an area of specific vegetation type. From the high-frequency (typically, 30 minute) imagery collected over several years, time series characterizing vegetation color, including canopy greenness, plus greenness rising and greenness falling transition dates, were summarized over 1- and 3-day intervals.

The data products, consisting of almost 1783 site-years of observations, can be used for phenological model validation and development, evaluation of satellite remote sensing data products, to understand relationships between canopy phenology and ecosystem processes, to study the seasonal changes in leaf-level physiology that are associated with changes in leaf color, for benchmarking earth system models, and for studies of climate change impacts on terrestrial ecosystems.

Acknowledgments:

The development of PhenoCam has been funded by the Northeastern States Research Cooperative, NSF's Macrosystems Biology program (awards EF-1065029 and EF-1702697), and DOE's Regional and Global Climate Modeling program (award DE-SC0016011). We acknowledge additional support from the US National Park Service Inventory and Monitoring Program and the USA National Phenology Network (grant number G10AP00129 from the United States Geological Survey), and from the USA National Phenology Network and North Central Climate Science Center (cooperative agreement number G16AC00224 from the United States Geological Survey).

2. Data Characteristics

Spatial Coverage: Multiple points mostly over North America, some sites in Panama, Hawaii, and Europe

Spatial Resolution: Point

Temporal Resolution: half-hourly, daily and 3 days

Temporal Coverage: 2000-02-11 to 2018-12-31

Spatial Extent: (All latitude and longitude given in decimal degrees)

Sites	Westernmost Longitude	Easternmost Longitude	Northernmost Latitude	Southernmost Latitude
Global	-158.15	119.22	71.28	22.97

Data File Information

File organization and data access

As described in the papers by Richardson et al. (2018) and Syednasrollah et al., 2019, the PhenoCam Dataset v2.0 consists of a set of 5 data records for each site. The data can be accessed directly in the ORNL DAAC data pool at https://daac.ornl.gov/data/global_vegetation/PhenoCam_V2/ (after login).

Files in the data pool are organized as follows.

data_record_1 (contains general metadata for each site)

- <sitename>_meta.json
- <sitename>_meta.txt

data_record_2 (contains the ROI list files and image mask files used for image processing)

- <sitename>_<veg_type>_<ROI_ID_number>_roi.csv
- <sitename>_<veg_type>_<ROI_ID_number>_<mask_index>.tif

data_record_3 (contains time series of ROI color statistics, calculated for each image in the archive, using data_record_2)

- <sitename>_<veg_type>_<ROI_ID_number>_roistats.csv

data_record_4 (contains time series of ROI color summary statistics, calculated for 1 and 3 day aggregation periods from data_record_3)

- <sitename>_<veg_type>_<ROI_ID_number>_1day.csv
- <sitename>_<veg_type>_<ROI_ID_number>_3day.csv

data_record_5 (contains phenological transition dates, calculated from data_record_4)

- <sitename>_<veg_type>_<ROI_ID_number>_1day_transition_dates.csv
- <sitename>_<veg_type>_<ROI_ID_number>_3day_transition_dates.csv

Here, <sitename> is the name of each camera site, <veg_type> is a two-letter code defining the type of vegetation for which data have been processed, and <ROI_ID_number> is a unique identifier to distinguish between multiple ROIs (regions of interest of the same vegetation type for a given site).

The PhenoCam data can also be downloaded from the dataset landing page (https://daacdataset.ornl.gov/cgi-bin/dsviewer.pl?ds_id=1674), where all 5504 data files are presented without the directory structure mentioned above. Specific sites or data file types can be selected using the filter box at the top right of the data file list. For example, all 32 data files for the Acadia National Park site in Maine can be retrieved by typing "acadia" in the filter box, checking the checkbox for "Select All" , and clicking on the "Add Checked Items" button below the table. The data files will then be delivered using the ORNL DAAC Shopping Cart.

data_record_1: PhenoCam network site descriptions

These files provide general metadata for the PhenoCam network sites from which processed imagery has been included in this data set. Following general project information, site specific location, contacts, date range, and environmental and ecological characteristics are listed. The fields are specified as key-value pairs.

There are 393 sites (files) in standard text format (*.txt) and named as: <**sitename**>_meta.txt where **sitename** is the name of the respective camera site, e.g., acadia_meta.txt. The 393 machine-readable JSON files are named as <**sitename**>_meta.json.

The variables within the text files are as follows:

Column	Description
last_updated	the date (format: YYYY-MM-DD, where MM = 01-12 and DD = 01-31) on which the site metadata were last updated
project	by default, all sites are associated with the PhenoCam Network project
project_url	the URL of the PhenoCam project web page
fairuse_statement	the general PhenoCam statement on data use, acknowledgment, and redistribution
project_fairuse_url	the URL of the PhenoCam fairuse_statement
sitename	the name of the camera site, e.g. "coweeta," used to designate all images and products associated with that site
long_name	a more descriptive name for each camera site
lat	the latitude (in decimal degrees) of the camera itself
lon	the longitude (in decimal degrees) of the camera itself
elevation	the elevation of the ground surface (m above sea level) at the camera site
contact1, contact2	the names and email addresses of the site representatives
active	"True" if new images from the site are still being added (as of last_updated date of the metadata file) to the PhenoCam archive; "False" otherwise

date_start	the date of the first image in the archive for this site
date_end	the date of the most recent image (as of the last_updated date of the metadata file) in the archive for this site (format: YYYY-MM-DD)
nimage	number of images in the archive for this site
site_type	the site class (Type I, II, or III)
ir_enabled	“Y” if the camera is capable of taking both visible and infrared (or visible+infrared) imagery
method	sites for which images are pushed to the PhenoCam server via FTP are designated “ftppush”, those for which images are pulled from an external server are designated “httppull”
utc_offset	the difference (in hours) between UTC (Coordinated Universal Time) and standard time at the site
camera_description	the brand and model of the camera being used
camera_orientation	the compass direction in which the camera is pointing
group	a number of camera sub-networks
flux_data	“True” if eddy covariance flux measurements are being (or have been) made at the site
flux_networks	if the site belongs to a network (e.g., AmeriFlux, Fluxnet-Canada, etc.), then the network is identified
flux_sitenames	FLUXNET site code, if applicable
ecoregion	numeric code identifying the site’s EPA Ecoregion
MAP_site	mean annual precipitation (mm) as reported by site personnel
MAP_daymet	mean annual precipitation (mm) from the Daymet
MAP_worldclim	mean annual precipitation (mm) from WorldClim
MAT_site	mean annual temperature (°C) as reported by site personnel
MAT_daymet	mean annual temperature (°C) from the Daymet
MAT_worldclim	mean annual temperature (°C) from WorldClim
primary_veg_type	the dominant vegetation type at the site
secondary_veg	secondary vegetation type at the site
dominant_species	Latin binomials for the dominant species at each site, as reported by site personnel
landcover_igbp	numeric code corresponding to the land cover classification scheme of the International Geosphere-Biosphere Programme, as derived from MODIS remote sensing Friedl et. al., 2010, Channan et al., 2014)
wwf_biome	numeric code corresponding to the biome classification scheme of the World Wildlife Fund (Olson et al., 2001)
koeppen_geiger	climate classification according to the Köppen-Geiger system (Kottek et al. 2006)

site_acknowledgments	data end users are asked to include this text, which has been provided by site collaborators, in publications and presentations that make use of data for this site
----------------------	---

data_record_2: ROI (Region of Interest) files

These files provide (1) the “ROI list files”, which detail the date and time range over which each binary image mask was applied in processing the image data for a site; and (2) the binary “image mask file”, which delineate the ROI over which the image analysis was conducted and (3) sample images for each image mask file. With (1) and (2) the data presented in the *_roistats.csv data files can be reproduced from the original image files.

There are 528 *_roi.csv ROI list files named as: **<sitename>_<veg_type>_<ROI_ID_number>_roi.csv**

Where **<sitename>** is the name of the network camera site, **<veg_type>** is a two-letter abbreviation identifying the dominant vegetation within the ROI, e.g. DB for deciduous broadleaf trees (see Table 1), and **<ROI_ID_number>** is a numeric code that serves as a unique identifier to distinguish between multiple ROIs of the same vegetation type at a given site (1000 for the first ROI list, 2000 for the second, etc.).

The first 13 lines (beginning with #), document the provenance of the ROI list, and contain a brief description of the vegetation that is delineated by the associated image masks. Line 14 lists the column headers for the mask entry rows.

Note that only images within the date and time ranges (from **start_date** and **start_time** to **end_date** and **end_time**) listed are included in the processed data set generated from this list. For **end_date**, the date code 9999-12-31 is used to keep the processing open-ended.

The column descriptions are as follows:

Column	Description
start_date	the date of the first image in the archive for this site
start_time	the time of capture of the first image for this site
end_date	the date of the most recent image (as of the last_updated date of the metadata file) in the archive for this site (format: YYYY-MM-DD)
end_time	the time of capture of the most recent image for this site
mask_file	the filename for the 8-bit TIFF mask file with black for the ROI and white for the region to exclude from calculations
sample_image	the filename for a sample image in the date range

ROI (Region of Interest) Mask and Image Files:

These are the binary “image mask files”, which delineate the ROI (black for the ROI and white for the region to exclude from calculations) over which the image analysis was conducted.

There are 1500 files in TIFF (*.tif) format and are named as **<sitename>_<veg_type>_<ROI_ID_number>_<mask_index>.tif** .

Where **<sitename>** is the name of the network camera site and **veg_type** is a two-letter abbreviation identifying the dominant vegetation within the ROI, e.g. DB for deciduous broadleaf trees,

ROI_ID_number is a numeric code that serves as a unique identifier to distinguish between multiple ROIs of the same vegetation type at a given site (1000 for the first ROI list, 2000 for the second, etc.) and the

mask_index matches the entry number in the list (01 for the first entry, 02 for the second entry, etc.).

For example, acadia_DB_1000_01.tif, ..., acadia_DB_1000_07.tif

The 1500 sample images for each mask file have the same naming convention but terminate in a .jpg extension:

<sitename>_<veg_type>_<ROI_ID_number>_<mask_index>.jpg

Vegetation-type abbreviations for ROIs

Vegetation type abbreviations for ROIs (region of interests).

Abbreviation	Description
AG	agriculture

DB	deciduous broadleaf
DN	deciduous needleleaf
EB	evergreen broadleaf
EN	evergreen needleleaf
GR	grassland
MX	mixed vegetation
SH	shrubs
TN	tundra
WT	wetland

data_record_3: Time Series of Color Information Extracted for Each ROI/Site Pair

These files contain the high-frequency (typically, 30 minute) color information extracted from the entire image archive for each site, using the ROI list files and image mask files note in the previous described data files.

For each archived image, RGB (red, green, blue) color channel information, with means and other statistics calculated across a region-of-interest (ROI) delineating a specific vegetation type was extracted. From the high-frequency (typically, 30 minute) imagery, time series characterizing vegetation color, including “canopy greenness”.

The providers refer to these as the “ROI statistics” time series files. The time series have not been filtered, and each data row in the file corresponds to an individual image in the archive.

There are 528 “ROI statistics” time series files named as <sitename>_<veg_type>_<ROI_ID_number>_roistats.csv

Where **sitename**, **veg_type**, and **ROI_ID_number** are the same as previous described.

File description for time series files:

The first 17 lines (beginning with #) contain basic metadata:

Line 4 contains the sitename, identical to that in the filename.

Lines 5 (veg_type) and 6 (ROI_ID_number) identify the vegetation type and the ROI_ID from the ROI list files.

Lines 7-9 are site location (latitude and longitude in decimal degrees, and elevation in m above sea level.

Line 10 is the UTC offset. [Lines 4-10 were extracted from the site metadata text files.]

Line 11 indicates whether images have been re- resized to common dimensions (to match the size of the mask file) prior to analysis.

Line 12 indicates the version of the data set.

Lines 13-16 document the provenance of the data file.

Line 18 lists the column headers for the data rows.

The data rows begin on line 19 with each data row corresponding to results for an individual image in the archive.

The column descriptions are as follows:

Column	Description
date	local date
local_std_time	local standard time
doy	day of year
filename	image filename

solar_elev	solar elevation angle, in degrees
exposure	image exposure
mask_index	mask number in the image mask sequence
gcc	mean green chromatic coordinate (Gcc) over the ROI
rcc	mean red chromatic coordinate (Rcc) over the ROI
r_mean	mean red channel DN over the ROI
r_std	standard deviation (across pixels) of red channel DN over the ROI
b_mean	mean blue channel DN over the ROI
b_std	standard deviation (across pixels) of blue channel DN over the ROI
g_mean	mean green channel DN over the ROI
g_std	standard deviation (across pixels) of green channel DN over the ROI
r_5_qtl	the 5th quantile values (across pixels) of the red channel DN over the ROI
r_10_qtl	the 10th quantile values (across pixels) of the red channel DN over the ROI
r_25_qtl	the 25th quantile values (across pixels) of the red channel DN over the ROI
r_50_qtl	the 50th quantile values (across pixels) of the red channel DN over the ROI
r_75_qtl	the 75th quantile values (across pixels) of the red channel DN over the ROI
r_90_qtl	the 90th quantile values (across pixels) of the red channel DN over the ROI
r_95_qtl	the 95th quantile values (across pixels) of the red channel DN over the ROI
b_5_qtl	the 5th quantile values (across pixels) of the blue channel DN over the ROI
b_10_qtl	the 10th quantile values (across pixels) of the blue channel DN over the ROI
b_25_qtl	the 25th quantile values (across pixels) of the blue channel DN over the ROI
b_50_qtl	the 50th quantile values (across pixels) of the blue channel DN over the ROI
b_75_qtl	the 75th quantile values (across pixels) of the blue channel DN over the ROI
b_90_qtl	the 90th quantile values (across pixels) of the blue channel DN over the ROI
b_95_qtl	the 95th quantile values (across pixels) of the blue channel DN over the ROI
g_5_qtl	the 5th quantile values (across pixels) of the green channel DN over the ROI
g_10_qtl	the 10th quantile values (across pixels) of the green channel DN over the ROI

g_25_qtl	the 25th quantile values (across pixels) of the green channel DN over the ROI
g_50_qtl	the 50th quantile values (across pixels) of the green channel DN over the ROI
g_75_qtl	the 75th quantile values (across pixels) of the green channel DN over the ROI
g_90_qtl	the 90th quantile values (across pixels) of the green channel DN over the ROI
g_95_qtl	the 95th quantile values (across pixels) of the green channel DN over the ROI
r_g_cor	correlation coefficient (across pixels) between red channel DN and green channel DN, over the ROI
g_b_cor	correlation coefficient between green channel DN and blue channel DN, over the ROI
b_r_cor	correlation coefficient between blue channel DN and red channel DN, over the ROI

data_record_4: 1- Day and 3- day Summary Product Files

1- day summary product files:

These files contain the daily summaries of the high-frequency (typically, 30 minute) time series data characterizing vegetation color, including “canopy greenness” for each site.

As noted previously, for each archived image, RGB (red, green, blue) color channel information, with means and other statistics calculated across a region-of-interest (ROI) delineating a specific vegetation type was extracted. From the high-frequency (typically, 30 minute) imagery, time series characterizing vegetation color, including “canopy greenness” was processed to 1-day intervals.

There are 528 1-day summary product files named as <sitename>_<veg_type>_<ROI_ID_number>_1day.csv. Where sitename, veg_type, and ROI_ID_number are the same as previous described.

File description for 1- day summary product files:

The first 24 lines (beginning with #) contain basic metadata.

Lines 4 through 10 are identical to those in the all-image time series file from which the summary product files are derived.

Line 11 is not used in the data sets but allows for the specification of an image count threshold for processing to occur (i.e., if for a given period of aggregation, there are insufficient images available, then only results for the midday image, if applicable, would be reported).

Line 12 gives the number of days that have been aggregated in producing the file, which is 1 day.

Line 13 reports the solar elevation filter that was used in processing (10° in the current data set).

Lines 14 and 15 are not used in the data sets but allows for the specification of time-of-day window (i.e., images outside of the window would be excluded from the processing).

Lines 16 and 17 report the values that were used for the “too dark” and “too bright” quality control filters, which are by default set to DN 100 and 665, respectively. Lines 18-23 document the provenance of the data file. Line 25 lists the column headers for the data rows.

The data rows begin on line 26, and for each data row the data fields are:

Column	Description
date	local date at the middle of the aggregation period (1-day)
year	calendar year of the above date (YYYY)
doy	day of year for the above date
image_count	the number of images passing the selection criteria
midday_filename	the filename of the image which is closest to 12 noon
midday_r	mean red channel DN over the ROI, for the midday image
midday_g	mean green channel DN over the ROI, for the midday image

midday_b	mean blue channel DN over the ROI, for the midday image
midday_gcc	the mean GCC over the ROI, for the midday image
midday_rcc	the mean RCC over the ROI, for the midday image
r_mean	the mean value (for all images passing the selection criteria) of the mean (by image) red channel DN over the ROI
r_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) red channel DN over the ROI
g_mean	the mean value (for all images passing the selection criteria) of the mean (by image) green channel DN over the ROI
g_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) green channel DN over the ROI
b_mean	the mean value (for all images passing the selection criteria) of the mean (by image) blue channel DN over the ROI
b_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) blue channel DN over the ROI
gcc_mean	the mean value (for all images passing the selection criteria) of the mean (by image) Gcc over the ROI
gcc_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) Gcc over the ROI
gcc_50, gcc_75, gcc_90	the 50th, 75th and 90th quantiles (for all images passing the selection criteria) of the mean (by image) GCC over the ROI
rcc_mean, rcc_std, rcc_50, rcc_75, rcc_90	the 50th, 75th and 90th quantiles (for all images passing the selection criteria) of the mean (by image) RGCC over the ROI
max_solar_elev	the maximum solar elevation angle for all images passing the selection criteria
snowflag	not included in this release
outlierflag_gcc_mean, outlierflag_gcc_50; outlierflag_gcc_75, outlierflag_gcc_90	the outlierflag, which is determined separately for the gcc_mean, gcc_50, gcc_75, and gcc_90 time series, can either take on a value of 0 (indicating good data), or 1 (indicating an outlier)
smooth_gcc_mean, smooth_gcc_50, smooth_gcc_75, smooth_gcc_90	the smoothed and/or interpolated value of Gcc from the final iteration (i.e. with outliers removed) of the spline fitting process
smooth_rcc_mean, smooth_rcc_50, smooth_rcc_75, smooth_rcc_90	the smoothed and/or interpolated value of Rcc from the final iteration (i.e. with outliers removed) of the spline fitting process
smooth_ci_gcc_mean, smooth_ci_gcc_50, smooth_ci_gcc_75, smooth_ci_gcc_90	the (one-sided) width of the 95% confidence interval around the smoothed GCC values
smooth_ci_rcc_mean, smooth_ci_rcc_50, smooth_ci_rcc_75, smooth_ci_rcc_90	the (one-sided) width of the 95% confidence interval around the smoothed RCC values
int_flag	to assist with identification of long gaps in the data record, the interpolation flag is set to 1 during a gap of 14 days or more

These files contain the 3-day summaries of the high-frequency (typically, 30 minute) time series data characterizing vegetation color, including “canopy greenness” for each site.

As noted previously, for each archived image, RGB (red, green, blue) color channel information, with means and other statistics calculated across a region-of-interest (ROI) delineating a specific vegetation type was extracted. From the high-frequency (typically, 30 minute) imagery, time series characterizing vegetation color, including “canopy greenness” was processed to 3-day intervals.

There are 528 3-day summary product files named as <sitename>_<veg_type>_<ROI_ID_number>_3day.csv. Where sitename, veg_type, and ROI_ID_number are the same as previous described.

File description for 3-day summary product files:

The first 24 lines (beginning with #) contain basic metadata.

Lines 4 through 10 are identical to those in the all-image time series file from which the summary product files are derived.

Line 11 is not used in the data sets but allows for the specification of an image count threshold for processing to occur (i.e., if for a given period of aggregation, there are insufficient images available, then only results for the midday image, if applicable, would be reported).

Line 12 gives the number of days that have been aggregated in producing the file, which is 3 days.

Line 13 reports the solar elevation filter that was used in processing (10° in the current data set).

Lines 14 and 15 are not used in the data sets but allows for the specification of time-of-day window (i.e., images outside of the window would be excluded from the processing).

Lines 16 and 17 report the values that were used for the “too dark” and “too bright” quality control filters, which are by default set to DN 100 and 665, respectively.

Lines 18-23 document the provenance of the data file.

Line 25 lists the column headers for the data rows.

The data rows begin on line 26, and for each data row the data fields are:

Column	Description
date	local date at the middle of the aggregation period (3-day)
year	calendar year of the above date (YYYY)
doy	day of year for the above date
image_count	the number of images passing the selection criteria
midday_filename	the filename of the image which is closest to 12 noon
midday_r	mean red channel DN over the ROI, for the midday image
midday_g	mean green channel DN over the ROI, for the midday image
midday_b	mean blue channel DN over the ROI, for the midday image
midday_gcc	the mean GCC over the ROI, for the midday image
midday_rcc	the mean RCC over the ROI, for the midday image
r_mean	the mean value (for all images passing the selection criteria) of the mean (by image) red channel DN over the ROI
r_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) red channel DN over the ROI
g_mean	the mean value (for all images passing the selection criteria) of the mean (by image) green channel DN over the ROI
g_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) green channel DN over the ROI
b_mean	the mean value (for all images passing the selection criteria) of the mean (by image) blue channel DN over the ROI

b_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) blue channel DN over the ROI
gcc_mean	the mean value (for all images passing the selection criteria) of the mean (by image) Gcc over the ROI
gcc_std	the standard deviation (for all images passing the selection criteria) of the mean (by image) Gcc over the ROI
gcc_50, gcc_75, gcc_90	the 50th, 75th and 90th quantiles (for all images passing the selection criteria) of the mean (by image) GCC over the ROI
rcc_mean, rcc_std, rcc_50, rcc_75, rcc_90	the 50th, 75th and 90th quantiles (for all images passing the selection criteria) of the mean (by image) RGCC over the ROI
max_solar_elev	the maximum solar elevation angle for all images passing the selection criteria
snowflag	not included in this release
outlierflag_gcc_mean, outlierflag_gcc_50; outlierflag_gcc_75, outlierflag_gcc_90	the outlierflag, which is determined separately for the gcc_mean, gcc_50, gcc_75, and gcc_90 time series, can either take on a value of 0 (indicating good data), or 1 (indicating an outlier)
smooth_gcc_mean, smooth_gcc_50, smooth_gcc_75, smooth_gcc_90	the smoothed and/or interpolated value of Gcc from the final iteration (i.e. with outliers removed) of the spline fitting process
smooth_rcc_mean, smooth_rcc_50, smooth_rcc_75, smooth_rcc_90	the smoothed and/or interpolated value of Rcc from the final iteration (i.e. with outliers removed) of the spline fitting process
smooth_ci_gcc_mean, smooth_ci_gcc_50, smooth_ci_gcc_75, smooth_ci_gcc_90	the (one-sided) width of the 95% confidence interval around the smoothed GCC values
smooth_ci_rcc_mean, smooth_ci_rcc_50, smooth_ci_rcc_75, smooth_ci_rcc_90	the (one-sided) width of the 95% confidence interval around the smoothed RCC values
int_flag	to assist with identification of long gaps in the data record, the interpolation flag is set to 1 during a gap of 14 days or more

data_record_5: Greenness Transition Date Estimate Files

These data files contain the transition date estimates for the start of each “greenness rising” stage and end of each “greenness falling” stage, derived from the 1-day and 3-day summary data.

There are 1056 date files.

The transition date files are named as:

<site name>_<veg_type>_<ROI_ID_number>_1day_transition_dates.csv, and
<site name>_<veg_type>_<ROI_ID_number>_3day_transition_dates.csv

Where **<site name>** is the name of the network camera site, **<veg_type>** is a two-letter abbreviation identifying the dominant vegetation within the ROI, e.g. DB for deciduous broadleaf trees (see Table 1), and **<ROI_ID_number>** is a numeric code that serves as a unique identifier to distinguish between multiple ROIs of the same vegetation type at a given site (1000 for the first ROI list, 2000 for the second, etc.).

File description for transition date files:

The first 16 lines (beginning with #) contain basic metadata.

Lines 4 through 6 are identical to those in the summary product file from which the transition date file is derived.

Line 7 gives the number of days that have been aggregated in producing the file, which is either 1 day (if transition dates are calculated from Data Record 4) or 3 days (if transition dates are calculated from Data Record 5).

Lines 8 and 9 define the first and last years for which the transition dates are calculated.

Lines 10 and 11 document the provenance of the data file.

Lines 12-15 report goodness-of-fit statistics (in terms of RMSE, the root mean squared error) for the spline curves from which the transition dates are extracted.

Line 17 lists the column headers for the data rows.

The data rows begin on line 18, and for each data row, corresponding to a single “greenness rising” or “greenness falling” stage.

Column	Description
sitename	the name of the camera site
veg_type	a two-letter abbreviation identifying the dominant vegetation within the ROI
roi_id	a numeric code (ROI_ID_number) to distinguish between multiple ROIs of the same vegetation type at a given site
direction	indicates whether the reported transition dates correspond to a “greenness rising” or “greenness falling” stage. Note that there may be more than one rising/falling cycle per calendar year, and a single rising or falling stage may cut across years.
gcc_value	indicates whether the transition dates are calculated from gcc_mean, gcc_50, gcc_75 or gcc_90 time series (a typical file will include dates calculated for each of these)
transition_10, transition_25, transition_50	the extracted transition dates (format YYYY-MM-DD) for each “greenness rising” or “greenness falling” stage, corresponding to 10%, 25% and 50% of the GCC amplitude of that stage
transition_10_lower_ci, transition_25_lower_ci, transition_50_lower_ci, transition_10_upper_ci, transition_25_upper_ci, transition_50_upper_ci	dates (format YYYY-MM-DD) corresponding to the lower and upper, respectively, 95% confidence intervals on the extracted transition dates (10%, 25%, and 50% of the GCC amplitude)
threshold_10, threshold_25, threshold_50	the threshold values of GCC used to identify transition dates
min_gcc, max_gcc	the baseline (dormant-season minimum) and peak (active-season maximum) GCC values, calculated from the fitted spline, as used to derive the GCC amplitude

3. Application and Derivation

Data derived from PhenoCam imageries can be used for phenological model validation and development, evaluation of satellite remote sensing data products, understand relationships between canopy phenology and ecosystem processes, to study the seasonal changes in leaf-level physiology that are associated with changes in leaf color, benchmarking earth system models, and studies of climate change impacts on terrestrial ecosystems (Richardson et al., 2018).

4. Quality Assessment

Quantitative analysis through automated quality control routines (e.g. filtering and outlier detection, described in Richardson et al., 2018) and visual evaluation of each time series has been vetted for consistency and overall quality (Richardson et al., 2018; Seyednasrollah et al., 2019)

5. Data Acquisition, Materials, and Methods

Following are brief excerpts from Richardson et al. (2018). See this publication for more details.

PhenoCam Network

The PhenoCam network is a cooperative network, established in 2008 and uses digital camera imagery to monitor ecosystem dynamics over time. It serves as a long-term, continental-scale, phenological observatory with cameras deployed within North America, from Alaska to Texas, and from Maine to Hawaii (Figure 2), and some on other continents.

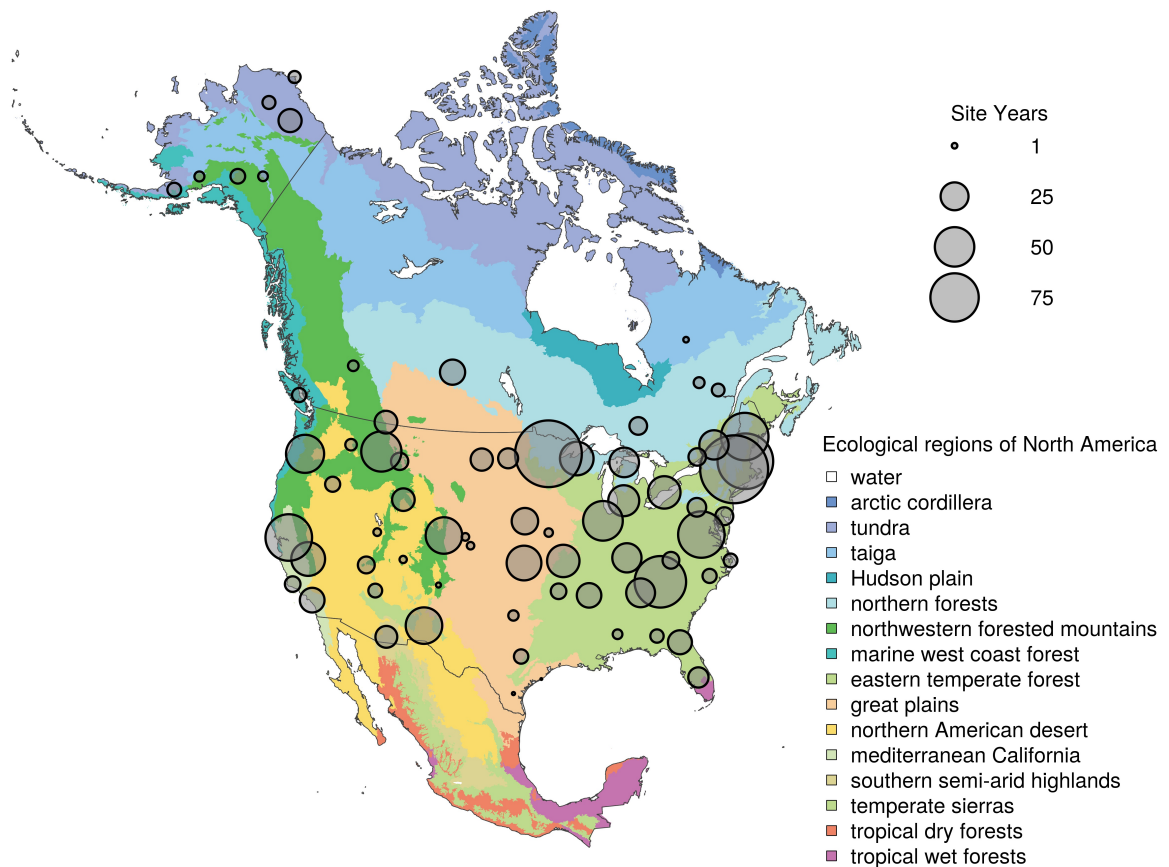

Figure 2: Spatial distribution of PhenoCam data across ecological regions of North America. Background map illustrates USA Environmental Protection Agency Level I Ecoregions. Data counts have been aggregated to a spatial resolution of 4°, and the size of each circle corresponds to the number of years of data. Sites outside of North America are not shown.

The data sets presented here are derived conventional, visible-wavelength, automated digital camera imagery from over 393 camera sites, together totaling almost 1783 years of data across different ecoregions, climate zones, and vegetation types. Vegetation types such as deciduous broadleaf forests (643 site-years of data in the dataset), grasslands (280 site-years), and evergreen needleleaf forests (265 site-years) are the best-represented. For each archived image, RGB (red, green, blue) color channel information, with means and other statistics calculated across a region-of-interest (ROI) delineating a specific vegetation type was extracted. From the high-frequency (typically, 30 minute) imagery, time series characterizing vegetation color, including canopy greenness (canopy greenness index -- the green chromatic coordinate, Gcc) processed to 1- and 3-day intervals was derived. For ecosystems with one or more annual cycles of vegetation activity, uncertainties, for the start of the “greenness rising” and end of the “greenness falling” stages has been provided. Every night, any new images that have been uploaded to the server during the previous 24 hours are copied to the data archive, and then processed and analysed as described in Richardson et. al., 2018. The processing is conducted using scripts coded in Python. The scripts used for image processing, including extraction of colour information, and generation of ‘all-image’ and ‘summary’ time series data product files, are available at <https://github.com/tmilliman/python-vegindex/> with an open source license agreement.

Image analysis and data processing

Image analysis consists of several steps. First, an appropriate “region of interest” (ROI) is defined, corresponding to the area within each digital image for which color information will be extracted. The ROIs characterize the dominant vegetation type in each image. For sites where more than one vegetation type could be clearly identified, secondary ROIs are selected. The ROI coordinate definitions are stored, in TIFF format, as a series of binary image masks, which comprise an ROI’s “mask sequence”. For each ROI mask sequence at each site, an “ROI list file” detailing the date and time range over which each mask is to be applied.

The digital cameras record JPEG images with color information stored in three separate layers (red, green, and blue; RGB). According to the standard additive color model, representation of any given color in the visible range is achieved by varying the intensity (pixel value) of these primary colors. Thus, each pixel in the image is associated with a digital number (“DN”) triplet, with each element in the triplet corresponding to the intensity of one of the color layers. Therefore, the second step in the image analysis is to read in the images, and associated mask sequence, and to characterize the frequency distribution of the RGB DN triplets across the mask. This is done separately for each ROI at each site, to produce the “ROI statistics” time series data files.

For each image, the date and local time were extracted from the image file name. In addition, the solar elevation angle based on the date and local time stamp, using standard formulas is also calculated.

The frequency distribution of the RGB DN triplets across the mask was characterized on a channel-by-channel basis, and also in terms of the pairwise correlation of DN values between color channels. Thus, for each of the red, green and blue color channels, the mean and standard deviation, as well as the 5th, 10th, 25th, 50th, 75th, 90th, and 95th quantiles, of the DN distribution across all pixels in the ROI was determined.

Transition Date Estimation

Using an approach similar to the “spline interpolation” method that has been previously applied to PhenoCam data, phenophase transition dates for each ROI mask sequence has been extracted. These are intended to define the start of the “greenness rising” and end of the “greenness falling” stage for a full cycle of vegetation activity (i.e., from dormancy, through green-up or “greenness rising”, peak activity, senescence or “greenness falling”, and back to dormancy).

6. Data Access

These data are available through the Oak Ridge National Laboratory (ORNL) Distributed Active Archive Center (DAAC).
